CEE6501 — Lecture 8.2

Support Settlement

Learning Objectives

By the end of this lecture, you will be able to:

- Model support settlements within the Direct Stiffness Method
- Derive the modified partitioned equations when $u_r \neq 0$
- Interpret settlement using imaginary restraints + superposition
- Relate settlement to an equivalent joint load
- Correctly compute member forces and reactions

Agenda

- **Part 1** — Conceptual Framework
- **Part 2** — Global Equations
- **Part 3** — Support Settlement, DSM Implementation
- **Part 4** — Truss Example

Part 1 — Conceptual Framework

Where Support Displacements Come From

In real structures, supports do not always remain perfectly fixed.

Small prescribed displacements may occur due to:

- Weak or compressible foundations
- Soil consolidation
- Differential settlement
- Fabrication tolerances or lack-of-fit

These are **imposed displacements**, not applied forces.

In DSM language:

$$u_r \neq 0$$

Core Question

How do we include prescribed support displacements within a force-based matrix framework?

DSM solves

$$Ku = F$$

Settlement does not directly enter as a force.

So we need a way to convert:

imposed displacements → equivalent forces

Key Idea

We use an imaginary fully restrained structure.

1. Restrain all joints.
2. Impose the prescribed settlements

$$\Delta_1,\ \Delta_2,\ \ldots$$

The fully fixed structure develops **fixed-joint forces**

$$F_1^S,\ F_2^S,\ F_3^S, \ldots$$

These are reactions required to enforce compatibility through superposition.

Superposition Process

We represent the actual system as:

$$
\begin{aligned}
&\text{Actual frame with settlement} \\
&= \\
&(1)\ \text{Imaginary Fully fixed frame with settlement, develops } F^S \\
&+ \\
&(2)\ \text{Real frame subjected to } -F^S
\end{aligned}
$$

(1) Imaginary Fully fixed Frame with Settlement

- Joints restrained
- Settlements imposed
- Fixed-joint forces develop

These forces represent the structural resistance to the imposed support movements.

(2) Real Frame Subjected to $-\boldsymbol{F}^S$

What Does This Mean Physically?

- The fully fixed system develops forces F^S
- Applying their negatives to the real frame cancels out the artificial restraints
- What remains is the true compatibility-driven response

The negatives of the fixed-joint forces therefore act as:

Equivalent joint loads due to settlement

These loads produce the same joint displacements as the actual support settlements.

Part 2 — Global Equations

Global Equilibrium

The assembled system (including fixed-end forces) is

$$Ku = F - F^F$$

Partition the system:

$$\begin{bmatrix} K_{ff} & K_{fr} \\ K_{rf} & K_{rr} \end{bmatrix} \begin{Bmatrix} u_f \\ u_r \end{Bmatrix} = \begin{Bmatrix} F_f \\ F_r \end{Bmatrix} - \begin{Bmatrix} F_f^F \\ F_r^F \end{Bmatrix}$$

Normally:

$$u_r = 0$$

With support settlement:

$$u_r \neq 0$$

Free DOFs Equation

From the first block row:

$$K_{ff}u_f + K_{fr}u_r = F_f - F_f^F$$

Rearranging:

$$K_{ff}u_f = F_f - F_f^F - K_{fr}u_r$$

Must calculate $K_{fr}u_r$

Physical Interpretation of $K_{fr}\,u_r$

What does the term $K_{fr}u_r$ represent?

- u_r = **prescribed displacements** at restrained DOFs (e.g., support settlements).
- $K_{fr}u_r$ = **forces induced at the free DOFs** by those imposed displacements.

Physically, this term represents the forces that would develop in the **free DOFs if they were temporarily held fixed while the supports moved**.

The K_{fr} Terms

$$\boldsymbol{K} = \left[\begin{array}{c:c} \boldsymbol{K}_{ff} & \boldsymbol{K}_{fr} \\ \hdashline \boldsymbol{K}_{rf} & \boldsymbol{K}_{rr} \end{array}\right] = \left[\begin{array}{cc:cccc} K_{33} & K_{35} & \boxed{K_{31}} & \boxed{K_{34}} & \boxed{K_{32}} & \boxed{K_{36}} \\ K_{53} & K_{55} & \boxed{K_{51}} & \boxed{K_{54}} & \boxed{K_{52}} & \boxed{K_{56}} \\ \hdashline K_{13} & K_{15} & K_{11} & K_{14} & K_{12} & K_{16} \\ K_{43} & K_{45} & K_{41} & K_{44} & K_{42} & K_{46} \\ K_{23} & K_{25} & K_{21} & K_{24} & K_{22} & K_{26} \\ K_{63} & K_{65} & K_{61} & K_{64} & K_{62} & K_{66} \end{array}\right]$$

Recall the definition of the stiffness coefficients:

$$k_{ij} = \text{force at DOF } i \text{ caused by a unit displacement at DOF } j, \\ \text{with all other DOFs fixed.}$$

In this example matrix (taken from Lecture 4):

- **Free DOFs:** $3, 5$ → i in K_{fr}
- **Restrained DOFs:** $1, 2, 4, 6$ → j in K_{fr}

Each column of K_{fr} represents the **forces at the free DOFs caused by a unit displacement at a restrained DOF**.

Instead of a unit displacement, we now apply the **actual prescribed displacement** (e.g., a support settlement).

The product, $K_{fr}u_r$, therefore gives the **forces induced at the free DOFs by the imposed support movements**.

These forces are analogous to the **fixed-joint forces**, F_f^S, because they correspond to the forces that would develop if the structure were **temporarily fixed at all DOFs** while the support DOFs were displaced.

Thus,

$$F_f^S = K_{fr}u_r$$

is the expression for the **fixed-joint force vector**, which is then **subtracted from the real system** to remove the artificial restraint in the superposition process.

Reactions

From the second block row of the partitioned system:

$$F_r = K_{rf} u_f + K_{rr} u_r + F_r^F$$

The term $K_{rr} u_r$ represents the **reactions generated directly by the imposed support displacements**.

When the supports move by u_r, the structure must develop forces to **satisfy displacement compatibility** at the restrained DOFs.

Big Picture Connection

Part 1 (Conceptual):

- Settlement → imaginary fully fixed structure
- Develop fixed-joint forces F^S
- Apply $-F^S$ to the real structure

Part 2 (Matrix Form):

- Settlement enters through u_r
- Fixed-joint forces to be subtracted appear as

$$F^S = K_{fr} u_r$$

No new theory is needed!

The superposition argument and the matrix formulation are the same mechanics as we used in definition FEFs in Lecture 6.

Part 3 — Support Settlement DSM Implementation

Code implementation steps

1. Assemble global K
2. Assemble applied load vector, F
3. Assemble fixed end force vector, F^F
4. Insert prescribed settlements into u_r
5. Partition matrices
6. Solve

$$u_f = K_{ff}^{-1}(F_f - F_f^F - K_{fr}u_r)$$

6. Compute reactions

$$F_r = K_{rf}u_f + K_{rr}u_r + F_r^F$$

7. Backward pass to recover element level forces

Part 4 — Truss Example

Example Problem (7.2 Kassimali)

Same truss structure we looked at back in Lecture 4.

```

Solution

Then transform **member end forces in local coordinates** to the **global coordinate system** using $f = T^T q$

The resulting global force components provide the **reactions at the supports** due to the prescribed support displacement.

Wrap-Up

Support settlement introduces **prescribed displacements at restrained DOFs**:

$$u_r \neq 0$$

The DSM equilibrium equation for the free DOFs becomes

$$K_{ff}u_f = F_f - F_f^F - K_{fr}u_r$$

The term $K_{fr}u_r$ represents the **forces induced at the free DOFs by the imposed support movements**.

Thus, support settlement enters the system as an **equivalent joint load**

$$F_f^S = K_{fr}u_r$$
